

03 Exploratory data analysis

Ágoston Reguly

Data Analysis 1: Exploration

2020

Motivation

Understand the market conditions for hotels in Vienna, using prices.

- ▶ How should you start the analysis itself?
- ▶ How to describe the data and present the key features?
- ▶ How to explore the data and check whether it is clean enough for (further) analysis?

Exploratory data analysis (EDA) - describing variables

5 reason to do EDA!

1. To check data cleaning (part of iterative process)
2. To guide subsequent analysis (for further analysis)
3. To give context of the results of subsequent analysis (for interpretation)
4. To ask additional questions (for specifying the (research) question)
5. Offer simple, but possibly important answers to questions.

Key tasks: describe variables

Look at key variables

- ▶ what values they can take and
- ▶ how often they take each of those values.
- ▶ are there extreme values

Describe what you see

- ▶ Descriptive statistics - key features summarized
- ↓
- ▶ to understand variables you work with
 - ▶ to make comparisons

Distribution - theory

A random variable (RV) can be fully characterized by its probability distribution function
- PDF - also called density function.

- ▶ Probability is a measure of the likelihood of an *event*.
- ▶ Probabilities are always between zero and one.
- ▶ PDF - connects all the possible event to a certain probability.

Theoretical vs Empirical distribution

In theory RV has a nice theoretical distribution - e.g. normal distribution. However in real life, we do not have infinitely many observations to have perfect theoretical distributions. We are only 'converging' to these distributions (see later - LLN, CLT).

In practice we have empirical distribution!

- ▶ The *frequency* or more precisely, *absolute frequency* or *count*, of a value of a variable is simply the number of observations with that particular value.
- ▶ The *relative frequency* is the frequency expressed in relative, or percentage, terms: the *proportion* of observations with that particular value among all observations.
- ▶ Practical note: With missing values – proportion can be relative to all observations OR only observations with non-missing values (usual choice).

More on probabilities and distributions

Probabilities and distributions are much wider notions, than we will use here. They are important if you want to prove some new data analysis tool to work (e.g. create a new estimator).

If you are interested here are some good textbook:

- ▶ Intro: Wooldridge (2018): Introductory Econometrics - Appendix B
- ▶ Intro: Greene (2011): Econometric Analysis - Appendix B
- ▶ Math intro: W. Feller (1968) An Introduction to Probability Theory and Its Applications, Vol. 1, 3rd Edition, Wiley
- ▶ Math hard core: R. Durrett (2010): Probability. Theory and Examples. 4th edition, Cambridge University Press

The distribution and the histogram

A key part of EDA is to look at (empirical) distribution of most important variables.

- ▶ All variables have a *distribution*.
- ▶ The distribution of a variable tells the frequency of each value of the variable in the data.
- ▶ May be expressed in terms of absolute frequencies (number of observations) or relative frequencies (percent of observations).
- ▶ The distribution of a variable completely describes the variable as it occurs in the data.
- ▶ independent from values the other variables may show.

Case Study: Hotel price histograms

(a) Absolute frequency (count)

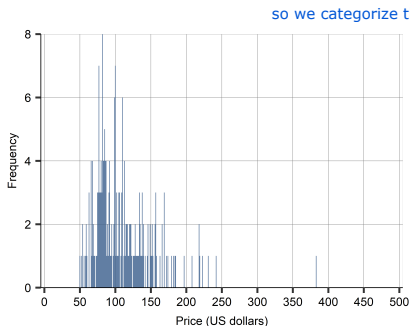

(b) Relative frequency (percent)

Source: `hotels-vienna` dataset. Vienna, Hotels only, for a 2017 November weekday

Case Study: Hotel price histograms

(a) Histogram: individual values

(b) Histogram: 20-euro bins

Note: Panel (a) just shows individual values - help see where most values are. Panel (b) is a histogram with 20-euro bins - more useful to capture frequencies. Source: `hotels-vienna` dataset. Vienna, 3-4 stars hotels only, for a 2017 November weekday

Case Study: Hotel price histograms

(a) Histogram: 40-euro bins

(b) Histogram: 80-euro bins

Note: Bin size matters. Wider bins suggest a more gradual decline in frequency.

Histograms

Histogram reveals important properties of a distribution.

- ▶ Number and location of *modes*: these are the peaks in the distribution that stand out from their immediate neighborhood.
- ▶ Approximate regions for *center* and *tails*
- ▶ *Symmetric* or not - asymmetric distributions have a long left tail or a long right tail
- ▶ *Extreme values*: values that are very different from the rest. Extreme values are at the far end of the tails of histograms.

skewd

Extreme values

- ▶ Some variables have extreme values: substantially larger or smaller values for one or a handful of observations than the values for the rest of the observations.
- ▶ Need conscious decision.
 - ▶ Is this an error? (drop or replace)
 - ▶ Is this not an error but not part of what we want to talk about? (drop)
 - ▶ Is this an integral feature of the data? (keep)

Case Study: Hotel density plot

- ▶ Vienna all hotels, 3-4 stars
- ▶ Use absolute frequency (count)
- ▶ For this histogram we use 0.5-km-wide bins. This way we can see the extreme values in more detail
- ▶ Dropped very far - likely not Vienna

Figure: Histogram of distance to the city center.

Case Study: Hotel prices

- ▶ Vienna all hotels, 3-4 stars
- ▶ Use absolute frequency (count)
- ▶ We go back to prices
- ▶ How to decide what to include? -> check observation!

Case Study: Hotel price histograms

(a) Histogram: 20-euro bins as seen

(b) Histogram: including extreme value above EUR 1000

Source: `hotels-vienna` dataset. Vienna, 3-4 stars hotels only, for a 2017 November weekday

Summary statistics

Histogram is great, but it does not provide quantitative measure of the distribution!

We have an idea how the empirical distribution looks like, but what are the key features?

Summary statistics

- ▶ For any given variable, a *statistic* is a meaningful number that we can compute from a dataset.
- ▶ Basic *summary statistics* describe the most important features of distributions of variables.
- ▶ Many of you know this. I briefly cover it, see more in Chapter 03

Summary statistics: Sample mean

久违了 样本统计量，原来你的英文名是这个

The most used statistic is the *mean*:

$$\bar{x} = \frac{\sum x_i}{n} \quad (1)$$

where x_i is the value of variable x for observation i in the dataset that has n observations in total. Two key features

$$\overline{x + a} = \bar{x} + a \quad (2)$$

$$\overline{x \cdot b} = \bar{x} \cdot b \quad (3)$$

The Expected value

- ▶ The expected value is the value that one can expect for a randomly chosen observation
- ▶ The notation for the expected value is $E[x]$.
- ▶ For a quantitative variable, the expected value is the mean
- ▶ For a qualitative variable, it can only be determined if transformed to a number
 - ▶ Male/Female binary variable. Expected value could be probability / relative frequency of females.
 - ▶ Quality of hotel: 1 to 5 stars, mean can be calculated, but its meaning is less straightforward.
 - ▶ What is the assumption for getting the mean as number?

Summary statistics: The median and other quantiles

- ▶ *Quantiles*: a quantile is the value that divides the observations in the dataset to two parts in specific proportions.
- ▶ The *median* is the middle value of the distribution - half the observations have lower value and the other half have higher value.
- ▶ *Percentiles* divide the data into two parts along a certain percentage.
 - ▶ The first percentile is the value below which one percent of the observations are and 99 percent above.
- ▶ *Quartiles* divide the data into two parts along fourths.
 - ▶ 1st quartile has one quarter of the observations below and three quarters above; it is the 25th percentile.
 - ▶ 2nd quartile has two quarters of the observations below and two quarters above; this is the median, and also the 50th percentile.

Summary statistics: The mode

- ▶ The *mode* is the value with the highest frequency in the data.
- ▶ Some distributions are unimodal, others have multiple modes.
- ▶ Multiple modes are apart from each other, each standing out in its "neighborhood", but they may have different frequencies.

Summary statistics: central tendency

- ▶ The mean, median and mode are different statistics for the *central value* of the distribution
- ▶ Central tendency.
 - ▶ The mode is the most frequent value
 - ▶ The median is the middle value
 - ▶ The mean is the value that one can expect for a randomly chosen observation.

Summary statistics: spread of distributions

- ▶ *spread of distributions* is also often used in analysis.
- ▶ Statistics that measure the spread of distributions are the range, inter-quantile ranges, the standard deviation and the variance. [Inter-quantile helps 'cause it explains 50% of the distrbution](#)
- ▶ The *range* is the difference between the highest value (the maximum) and the lowest value (the minimum) of a variable.
- ▶ The *inter-quantile ranges* is the difference between two quantiles- the third quartile (the 75th percentile) and the first quartile (the 25th percentile).
- ▶ The 90- 10 percentile range gives the difference between the 90th percentile and the 10th percentile.

Summary statistics: standard deviation

- ▶ The most widely used measure of spread is the *standard deviation*. Its square is the *variance*.
- ▶ Variance is the average squared difference of each observed value from the mean.
- ▶ The standard deviation captures the typical difference between a randomly chosen observation and the mean.
- ▶ The variance is a less intuitive measure. At the same time, the variance is easier to work with, because it is a mean value itself.

$$\text{Var}[x] = \frac{\sum (x_i - \bar{x})^2}{n} \quad (4)$$

$$\text{Std}[x] = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n}} \quad (5)$$

Summary statistics: skewness

- ▶ A distribution is *skewed* if it isn't symmetric.
- ▶ It may be skewed in two ways, having *a long left tail* or having *a long right tail*.
- ▶ Example: hotel price distributions having a long right tail - such as in hotel price distribution.
- ▶ Skewness and the prevalence of extreme values are related. With distributions with long tails, values far away from all other values are more likely.
- ▶ When extreme values are important for the analysis, skewness of distributions is important, too.

Summary statistics: skewness measure

Simplest measure is *mean–median measure of skewness*.

$$Skewness = \frac{(\bar{x} - median(x))}{Std[x]} \quad (6)$$

- ▶ When the distribution is symmetric its mean and median are the same.
- ▶ When it is skewed with a long right tail the mean is larger than the median: the few very large values in the right tail tilt the mean further to the right.
- ▶ When a distribution is skewed with a long left tail the mean is smaller than the median
- ▶ To make this measure comparable across various distributions use a standardized measure
- ▶ If multiplied by 3, and then it's called *Pearson's second measure of skewness*.

Case study: Vienna vs London

- ▶ Compare two cities, how hotel markets vary
- ▶ Vienna, London
- ▶ 3-4 star hotels, only "Hotels" (no apartments), below 1000 euros.
- ▶ Focus on actual city=Vienna and actual city=London (exclude nearby related villages).
- ▶ Use `hotels-europe` dataset.
- ▶ N=207 for Vienna, N=435 for London

Case Study: London vs Vienna

Figure: Vienna Austria

Figure: London, UK

Density plots

- ▶ *Density plots* - also called *kernel density estimates*
- ▶ alternative to histograms - instead of bars density plots show continuous curves.
- ▶ Instead of bars, density plots show continuous curves. We may think of them as curves that wrap around the corresponding histograms.
- ▶ density plots complementing histograms - some believe density plots allow for easier comparison of distributions across groups in the data.

Case study: The density plot

- Density plot
- Less reliable than histogram
- But key points good be read off
- Easy when comparison

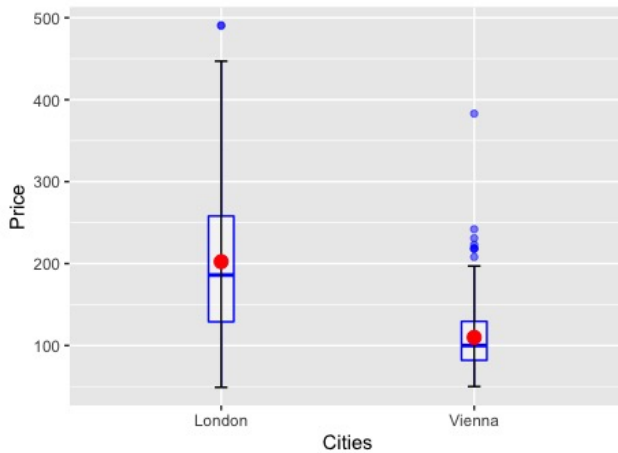

Case Study: Case study hotels: descriptive statistics

Table: Descriptive statistics for hotel prices in two cities.

city	n	mean	median	min	max	sd	skew
London	435	202.36	186	49	491	88.13	0.186
Vienna	207	109.98	100	50	383	42.22	0.236

Source: `hotels-europe` dataset. Vienna and London, weekday,
November 2017

Case Study: Case study hotels: Box plot

Theoretical distributions

Theoretical distributions are distributions of variables with idealized properties.

- ▶ Show frequencies for theoretical distributions and not for empirical's.
- ▶ The likelihood of each value in a more abstract setting - hypothetical "dataset" or "population," or the abstract space of the possible realizations of events.
- ▶ Theoretical distributions are fully captured by few *parameters*: these are statistics determine the whole distributions

Theoretical distributions

Theoretical distributions can be helpful

- ▶ Have well-known properties!
- ▶ If variable in our data well approximated by a theoretical distribution → attribute properties to the variable
- ▶ Real life, many variables surprisingly close to theoretical distributions.
- ▶ Will be useful when generalizing from data - **Class 05**

The Normal distribution

- ▶ Histogram is bell-shaped
- ▶ Outcome (event), can take any value
- ▶ Distribution is captured by two parameters
 - ▶ μ is the mean
 - ▶ σ the standard deviation
- ▶ Symmetric = median, mean (and mode) are the same.
- ▶ Example: height of people, IQs, ect.

The log-normal distribution

- ▶ Asymmetrically distributed with long right tails.
- ▶ start from a normally distributed RV (x), transform it: (e^x) and the resulting variable is distributed log-normal.
- ▶ Always non-negative
- ▶ Example distributions of income, or firm size.

A few more points on the Normal and log-normal

- ▶ Many many variables in real life are close to normal
- ▶ Especially when based on elementary things which are added up
- ▶ Not good approximation when
 - ▶ some reasons for non-symmetry
 - ▶ extreme values are important
- ▶ Variables are well approximated by the log-normal if they are the result of many things *multiplied* (the natural log of them is thus a sum).

Case Study: Income and log-income

Figure: income

log-normal distribution

Figure: log income

normal distribution

The power law distribution

- ▶ Also called as Pareto distribution
- ▶ Very large extreme values - well approximated
- ▶ Relative frequency of close-by values are the same along large and small values
- ▶ Real world: many examples, but often not the whole distribution
- ▶ Example: frequency of words, city population, wealth

Summary

- ▶ Always check your key variables
- ▶ Look at summary statistics, understand key features such as central tendency, spread and skewness
- ▶ Look at histograms to get a broader picture of the distribution, see if multiple modes or extreme values.
- ▶ Is the distribution you see close to a well-know theoretical distribution such as normal, log-normal or Power-law? If yes, it could be useful for analysis!

Summary steps of EDA

1. First focus on the most important variables. Go back to look at other variables if subsequent analysis suggests to.
2. For qualitative variables, list relative frequencies.
3. For quantitative variables, look at histograms. May decide for transformation, find extreme values, learn about key aspects of data.
4. Check for extreme values. Decide what to do with them.
5. Look at summary statistics. It may prompt actions, such as focusing on some part of the dataset.
6. Do further exploration if necessary (time series data, comparisons across groups of observations, etc.)

Summary steps of EDA - Vienna hotels

1. Start with full data $N=428$
2. Tabulate key qualitative variables
3. accommodation type - could be apartment, etc. Focus on hotels. $N=264$
4. stars - focus on 3, 3.5 4 stars, as lower bit not well covered, luxury could vary a lot. $N=218$
5. Look at quantitative variables, focus on extreme values.
6. Start with price. $p=1012$ likely error drop. keep others $N= 217$
7. Distance: some hotels are far away. define cutoff. drop beyond 8km $N=214$
8. check why hotels could be far away. Find variable city_actual. Tabulate. Realise few hotels are not in Vienna. Drop them. $N=207$
9. So, the final cut: Hotels, 3 to 4 stars, below 1000 euros, less than 8km from center, in Vienna actual $N=207$.

Good graphs: Guidelines for decisions in data visualization

- ▶ Here: some basics
- ▶ Please read textbook section
- ▶ We will practice in R coding class

Data visualization

- ▶ We shall make conscious decisions and not let default settings guide us.
- ▶ We break our preferences into four layers:
 1. usage - what you want to show and to whom – deciding on purpose, focus, and audience
 2. encoding - key elements of the graphs showing how you want to present the message
 3. scaffolding - how you want to present elements that support understanding such as axis and legends
 4. annotation - adding anything else you want to emphasize

Data visualization: usage

- ▶ what message you want to convey and to whom?
- ▶ As a general principle, one graph should convey one message.
- ▶ Be explicit about the purpose of the graph and the target audience: general audience vs specialist
- ▶ For a specialist audience, more complicated graphs are okay.

Data visualization: encoding

- ▶ how to show what you want to show.
- ▶ picking the type of graph, additional features to it, and colors.
- ▶ type of graph: bar chart, scatterplot, etc.
- ▶ How to denote information (dots, lines, bars)
- ▶ Have an additional encoding to help comparison: bar chart for separate groups encoded with colors.
- ▶ One information, one encoding - use size or color but not both.

Data visualization: scaffolding

- ▶ How to present elements that support understanding.
- ▶ Make sure, a graph has
 - ▶ Title
 - ▶ Axis title and labels
 - ▶ Legend
- ▶ Content as well as format, such as font type and size.

Data visualization: annotations

- ▶ if there is something else we want to emphasize.
- ▶ additional information can help put the graph into context or emphasize some part of it
- ▶ Colored area, circled observations, arrow+text, etc

Data visualization: example

- ▶ Usage: to show distribution for general audience
- ▶ Encoding is bars (histogram), bin size set at 20
- ▶ Axes labelled with title + grid
- ▶ annotation: far away hotels
