# 06 Testing hypotheses

Agoston Reguly

Data Analysis 1: Exploration

2020

# Housekeeping

- ▶ Due to delay in coding Extra points can be submitted until 25th of October.
- ► Change in schedule:
  - ▶ 21th of October (next week Wednesday) we have Coding in R class instead of DA2
  - ▶ 25th of November, we will have the DA2 instead of Coding in R

06 Testing hypotheses 2 / 42 Agoston Reguly

#### Exam

- > 75 minutes closed book exam
- ► Maximum score is 100
- ► Two parts:
  - ▶ 8 short answer questions, each worth 10 points
    - ▶ E.g. Hotel user ratings is qualitative variable ranging between 1 and 5. Describe in words what it means that hotel prices and hotel ratings are positively correlated. (4p) What does it mean that prices and distance from airport is not correlated? (2p) How would a scatterplot of price and rating look like? (4p)
  - ▶ 10 True/false questions, each worth 2 points
    - ► E.g. The covariance is a standardized measure of the correlation coefficient using the standard error of both variables.
- ► For pass need to get 50 points.
- ▶ Practice with practice questions at the end of each chapter.

06 Testing hypotheses 3/42 Agoston Reguly

#### Motivation

▶ The internet allowed the emergence of specialized online retailers while larger shops also sell goods on the main street as well. How to measure price differentiation by online and offline prices? To help answer this, we can collect and compare online and offline prices of the same products and test if the averages are the same.

06 Testing hypotheses 4 / 42 Agoston Reguly

# The logic of hypothesis testing

- ▶ A hypothesis is a statement about a general pattern, of which we are not sure if it is true or not.
- ▶ Hypothesis testing = analyze our data to make a decision based on the hypothesis.

- Reject the hypothesis if there is enough evidence against it.
- Don't reject it if there isn't enough evidence against it.
- We do not have enough evidence against a hypothesis
  - ▶ if the hypothesis is in fact true
  - or it is not true, but our evidence is weak
- ► Important asymmetry: rejecting a hypothesis is a more conclusive decision than not rejecting it!

06 Testing hypotheses 5 / 42 Agoston Reguly

# The logic of hypothesis testing: the setup

- ▶ Define the *the statistic we want to test*. Let us call it *s* (e.g. mean).
- $\blacktriangleright$  We are interested in the true value of s noted as  $s_{true}$ .
- $\blacktriangleright$  The value the statistic in our data is its estimated value, denoted by a hat on top  $\hat{s}$ .

06 Testing hypotheses 6 / 42 Agoston Reguly

# The logic of hypothesis testing: H0 vs HA

- Formally stating the question as two competing hypotheses of which only one can be true: a null hypothesis  $H_0$  and an alternative hypothesis  $H_{\Delta}$ .
- ► Formulated in terms of the unknown true value of the statistic.
- ► The null specifies some value or range; the alternative specifies *all other* possible values.
- ▶ Together, the null and the alternative cover all the possibilities we are interested in.
- One example:

$$H_0: s_{true} = 0$$

$$H_{\Delta}: S_{true} \neq 0$$

06 Testing hypotheses 7 / 42 Agoston Reguly

# The logic of hypothesis testing: The criminal court example

- ▶ Logic of testing like a criminal court procedure.
  - ▶ Decide if the accused is guilty or innocent of a certain crime.
  - Assumption of innocence: accused judged guilty only if enough evidence against innocence
  - ▶ Even though the accused in court because of suspicion of guilt.
- ► The null is "protected": it has to be hard to reject it otherwise the conclusions of hypothesis testing would not be strong.
- ► To translate this procedure to the language of hypothesis testing,
  - $ightharpoonup H_0$  is that the person is innocent
  - $\blacktriangleright$   $H_A$  is that the person is guilty.

06 Testing hypotheses 8 / 42 Agoston Reguly

# The logic of hypothesis testing: two vs. one-sided test

- ► Two-sided alternative:
  - ▶ We test if  $H_A$ :  $s_{true} \neq 0$  allows for  $s_{true}$  to be either greater than zero or less than zero. Not interested if the difference is positive or negative.
- One-sided alternative
  - interested if a statistic is positive or not.
- ▶ Different setup: the hypothesis we are testing is focusing to the alternative set.

One-sided test.

$$H_0: s_{true} \leq 0$$

$$H_A: s_{true} > 0$$

06 Testing hypotheses 9 / 42 Agoston Reguly

- ▶ Question: Do the online and offline prices of the same products differ on average?
- ▶ Data includes 10 to 50 products in each retail store included in the survey (the largest retailers in the U.S. that sell their products both online and offline).
- ► The products were selected by the data collectors in stores, and they were matched to the same products the same stores sold online.
- Let define our statistic as the difference in average prices.

06 Testing hypotheses 10 / 42 Agoston Reguly

- ► Statistics we are interested: difference in prices
- ▶ Each product i has both an online  $(p_{i,online})$  and an offline  $(p_{i,offline})$  price in the data.
- ► The difference is:

Hypothesis

$$pdiff_i = p_{i,online} - p_{i,offline}$$

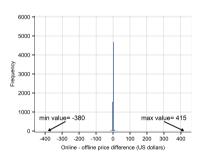

The statistic we are interested in with n observations is:

$$\hat{s} = \overline{pdiff} = \overline{p_{online}} - \overline{p_{offline}} = \frac{1}{n} \sum_{i=1}^{n} (p_{i,online} - p_{i,offline})$$

06 Testing hypotheses 11 / 42 Agoston Reguly

#### Descriptive statistics of the difference

- ► The mean difference is -0.05\$: online prices are, on average, 5 cents lower in this dataset.
- ➤ Spread around this average: Standard deviation is 10\$
- ► Extreme values matter: Range: -380\$ +415\$.
- ➤ Out of the 6,439 products, 64% have the same online and offline price, for 87%, the difference within ±1 dollars

06 Testing hypotheses 12 / 42 Agoston Reguly

# Case Study - Comparing online and offline prices: Formalizing the question

Do average prices differ in the general pattern represented by the data?

$$H_0: s_{true} = \bar{p}_{online\ true} - \bar{p}_{offline\ true} = 0$$

$$H_A$$
:  $s_{true} = \bar{p}_{online\ true} - \bar{p}_{offline\ true} \neq 0$ 

06 Testing hypotheses 13 / 42 Agoston Reguly

# The logic of hypothesis testing

- ▶ The t-test is the testing procedure based on the *t-statistic* 
  - t-statistic comes from a sampling distribution which is distributed as a standardized 'Student's-t' distribution.
- We compare the estimated value of the statistic  $\hat{s}$  (our best guess of s) to our null-hypothesis.
- $\triangleright$  Evidence to reject the null: difference between  $\hat{s}$  and our null-hypothesis is large.
- Not reject the null if the estimate is not very far, i.e., when there is not enough evidence against it.

06 Testing hypotheses 14 / 42 Agoston Reguly

#### T-test

- ▶ The *t-statistic* is a statistic that measures the distance of the estimated value from what the true value would be if  $H_0$  was true.
- ▶ Uses sample estimates  $\hat{s}$  and the standard error of the estimate,  $SE(\hat{s})$ . Let

$$H_0: s_{true} = 0,$$
  
 $H_A: s_{true} \neq 0$ 

► The t-statistic for this hypotheses is:

$$t = \frac{\hat{s}}{SE(\hat{s})}$$

▶ The test statistic summarizes all the information needed to make the decision.

06 Testing hypotheses 15 / 42 Agoston Reguly

#### Most important t-tests

When the  $H_0$  is: the average is equal to zero, the t-statistic is simply

$$t = \frac{\bar{x}}{SE(\bar{x})} \tag{1}$$

When the  $H_0$  is: the average is equal to a specific number, the t-statistic is

$$t = \frac{\bar{x} - number}{SE(\bar{x})} \tag{2}$$

When  $H_0$  compares two averages:  $\bar{x}_A - \bar{x}_B = 0$ , the t-statistic is

$$t = \frac{\bar{x}_A - \bar{x}_B}{SE(\bar{x}_A - \bar{x}_B)} \tag{3}$$

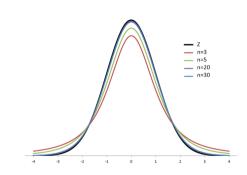

06 Testing hypotheses 16 / 42 Agoston Reguly

#### t-statistics under the null

"Under the null" or if the  $H_0$  is true, the *t-statistics* comes from a sampling distribution which is distributed as 'Student's-t' distribution.

- Student's-t is similar to the standard normal distribution.
- ▶ It has mean zero and standard deviation of 1.
- ► It has a third parameter 'degree of freedom' which in our case relates to the number of observations.

What is the likelihood that our t-statistic (t) comes from this distribution?

06 Testing hypotheses 17 / 42 Agoston Reguly

### Making a decision

- In hypothesis testing the decision is based on a clear rule *specified in advance*.
- ▶ A decision rule makes the decision straightforward and transparent.
- Helps avoid personal bias: put more weight on the evidence that supports our prejudices.
- ▶ Clear decision rules are designed to minimize the room for such temptations.

06 Testing hypotheses 18 / 42 Agoston Reguly

# Making a decision

- ▶ The decision rule = comparing the test statistic to a pre-defined *critical value*.
- ▶ Is test statistic is large enough to reject the null?
- ▶ Null rejected if the test statistic is larger than the critical value.
- Critical value governs the trade-off between being too strict or too lenient with our decision.

06 Testing hypotheses 19 / 42 Agoston Reguly

# Being right or wrong

When we make the decision, we may be right or wrong in two ways.

	$H_0$ is true	$H_0$ is false
Don't reject the null	True negative	False negative - Type II error
Reject the null	False positive - Type I error	True positive

06 Testing hypotheses 20 / 42 Agoston Reguly

### Making an error

- ▶ We say that our decision is a *false positive* if we reject the null when it is true.
  - "positive" because we take the active decision to reject the protected null.
  - medical: person has the condition that they were tested against
  - ► False positive = type-I error;
- Our decision is a *false negative* if we do not reject the null even though we should.
  - "negative" because we do not take the active decision
  - ▶ medical: result is "negative" = not have the condition
  - ► False negative =type-II error.

06 Testing hypotheses 21 / 42 Agoston Reguly

### Protecting against Type-I error

- ▶ False positives and false negatives: both wrong, but not equally.
- ► Testing procedure protects the null: reject it only if evidence is strong
- ► The background assumption wrongly rejecting the null (a false positive) is a bigger mistake than wrongly accepting it (a false negative).
- ▶ Decision rule (critical value) is chosen in a way that makes false positives rare.

06 Testing hypotheses 22 / 42 Agoston Reguly

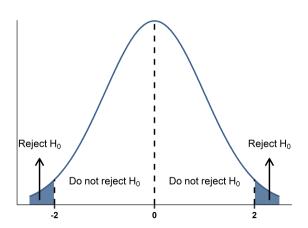

# Rule of thumb when making a decision

- $\blacktriangleright$  A commonly applied critical value for a t-statistic is  $\pm 2$ :
  - $\triangleright$  reject the null if the t-statistic is smaller than -2 or larger than +2;
  - $\triangleright$  don't reject the null if the t-statistic is between -2 and +2.
- ▶ Prob(t-statistic < -2) or Prob(t-statistic > 2) are both appr 2.5%
- ▶ If the null is true: Probability t-statistic is below -2 or above +2 is 5%
- With  $\pm 2$  critical value 5% is the probability of false positives we have 5% as the probability that we would reject the null if it was true (False positive).
- ▶ If we make the critical values -2.6 and +2.6 the chance of the false positive is 1%.

06 Testing hypotheses 23 / 42 Agoston Reguly

#### Sampling distribution of the test statistic when the null is true

- ▶ Distribution of the t-statistic would be close to standard normal N(0,1), if we have medium sample size
- Prob t-statistic < −2 or > 2 is approximately 2.5%. Prob t-statistic is < −2 or > +2 is 5% if the null is true. (Two-sided alternative)
- ➤ 5% = probability of false positives if we apply the critical values of ±2

06 Testing hypotheses 24 / 42 Agoston Reguly

#### Critical values and generalization

- ► Can set other critical values that correspond to different probabilities of a false positive.
- ► That choice of 5% means that we tolerate a 5% chance for committing false positive error
- ▶ Data analysts avoid biases when testing hypotheses: use the same critical value regardless of the data and hypothesis they are testing.

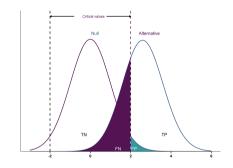

06 Testing hypotheses 25 / 42 Agoston Reguly

### False negative

► Fixing the chance of false positives affects the chance of false negatives at the same time.

► A false negative arises when the t-statistic is

- within the critical values and we don't reject the null even though the null is not true.
- Making a false negative call is more likely when it is harder to make a decision
  - Sample is small
  - ► The difference between true value and null is small

06 Testing hypotheses 26 / 42 Agoston Reguly

# Size and power of the test

#### Under the null:

- ▶ Size of the test: the probability of committing a false positive.
- ▶ Level of significance: The maximum probability of false positives we tolerate.

When we fix the level of significance at 5% and end up rejecting the null, we say that the statistic we tested is significant at 5%

#### Under the alternative:

- Power of the test: the probability of avoiding a false negative
- ▶ Being different from the null can be in many ways...
- ► High power is more likely when
  - ► The sample is large and the dispersion is small.
  - ▶ The further away the true value is from what's in a null.

We usually fix the level of significance at 5% and hope for a high power of the test.

06 Testing hypotheses 27 / 42 Agoston Reguly

# The p-value

- ▶ The p-value makes testing easier captures information for reject/accept calls.
  - ▶ Instead of calculating test statistics and specify critical values, we can make an informed decision based on the p-value only.
- ightharpoonup p-value is the smallest significance level at which we can reject  $H_0$  given the value of the test statistic in the sample.
- ▶ The p-value tells us the largest probability of a false positive.
- ► The p-value depends on
  - 1. the test statistic.
  - 2. the sampling distribution of the test statistic

06 Testing hypotheses 28 / 42 Agoston Reguly

### The p-value

- ▶ If the p-value is 0.05 the maximum probability that we make a false positive decision is 5%.
- ▶ If we are willing to take that chance, we should reject the null; if we aren't, we shouldn't.
- ▶ If the p-value is, say, 0.001 there is at most a 0.1% chance of being wrong if we were to reject the null.
- ▶ We can never be absolute certain! p-value is never zero.
- ► For a reject/accept decision, one should pick a level of significance before the test.
- ▶ What we can accept depends on the setting: what is the cost of a false positive.

06 Testing hypotheses 29 / 42 Agoston Reguly

- Let's fix the level of significance at 5%.
- ▶ Doing so we tolerate a 5% chance for a false positive.
- ▶ Allow a 5% chance to be wrong if we reject the null hypothesis of zero average price difference.
- $\blacktriangleright$  A 5% level of significance translates to  $\pm 2$  bound for the t-statistic.
- ▶ The value of the statistic in the dataset is -0.054. Its standard error is 0.124.
- $\blacktriangleright$  Thus the t-statistic is 0.44. This is well within  $\pm 2$ .
- ▶ Don't reject the null hypothesis of zero difference.
- ▶ We do *not* say we proved it's zero!!! We showed we cannot tell it different from zero.

06 Testing hypotheses 30 / 42 Agoston Reguly

- ► Conclude that the average price difference is not different from zero in the general pattern represented by the data.
- Large dataset, good power. What we see in t-statistic is not because of very small sample size.
- ▶ It is still possible that prices are indeed different, just the difference is very small.
- ► Economically speaking, a few cent difference would not matter.

06 Testing hypotheses 31 / 42 Agoston Reguly

- ► The p-value of the test is 0.66.
- ► That means that the smallest level of significance at which we can reject the null is 66%.
- ▶ The chance that we would make a mistake if we rejected the null is at most 66%.
- So we don't reject the null

06 Testing hypotheses 32 / 42 Agoston Reguly

#### Multiple testing

- ► Medical dataset: data on 400 patients
- ► A particular heart disease binary variable and 100 feature of life style (sport, eating, health background, socio-economic factors)
- ► Look for a pattern is the heart disease equally likely for poor vs rich, take vitamins vs not, etc.
- ► You test one-by-one
- ▶ You find that for half a dozen factors, there is a difference
- Any special issue?

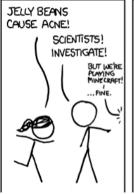

06 Testing hypotheses 33 / 42 Agoston Reguly

### Multiple testing

- ► The pre-set level of significance / p-value are defined for a single test
- In many cases, you will consider doing many many tests.
  - ▶ Different measures (mean, median, range, etc)
  - ▶ Different products, retailers, countries
  - ▶ Different measures of management quality

For multiple tests, you cannot use the same approach as for a single one.

WE. FOUND NO LINK BETWEEN ORANGE JELLY BEANS AND ACNE (P>0.05).

06 Testing hypotheses 38 / 42 Agoston Reguly

#### Multiple testing

- Consider a situation in which we test 100 hypotheses.
- Assume that all of those 100 null hypotheses are true.
- ▶ Set significance we accept 5% chance to be wrong when rejecting the null. That means that we tolerate if we are wrong 5 out of 100 times.
- We can expect the null to be rejected 5 times when we test our 100 null hypotheses, all of which are true.
- In practice that would appear in 5 out of the 100 tests
- We could pick those five null hypotheses and say there is enough evidence to reject.
- ▶ But that is wrong: we started out assuming that all 100 nulls are true.
- ➤ Simply by chance, we will see cases when we would reject the null, but we should not -> committing false positive error!

06 Testing hypotheses 39 / 42 Agoston Reguly

#### Multiple testing

- ► There are various ways to deal with probabilities of false positives when testing multiple hypotheses.
- Often complicated.
- ➤ Solution 1: If you have a few dozens of cases, just use a strict criteria (such as 0.1-0.5% instead than 1-5%) for rejecting null hypotheses.
- ► A very strict such adjustment is the Bonferroni correction that suggests dividing the single hypothesis value by the number of hypotheses.
  - ► For example, if you have 20 hypotheses and aim for a p=.05
  - reject the null only if you get a p=0.05/20=0.0025
  - ► It is typically too strict

06 Testing hypotheses 40/42 Agoston Reguly

# p-hacking

*P-hacking*: Showing only results of hypothesis tests that suggest one decision when different choices in the data wrangling would lead to different conclusions.

- ► Handling of missing values
- ► Dealing with extreme values
- Conditioning on such x's
- Dropping observations

All these leads to 'set' the p-value such that you have your wanted result...

These methods are wrong and undermine the profession!

06 Testing hypotheses 41 / 42 Agoston Reguly

# Testing when data is very big

- ▶ With very large dataset some aspects of statistical inference lose their relevance.
- ▶ When the data has millions of observations generalizing to the general pattern does not add much.
- ► That is true for testing hypotheses, too.
- ▶ If, for example, two averages calculated from millions of observations are different to a meaningful extent they are almost surely different in the general pattern represented by the dataset.
- ▶ So: if you have millions of observations, just look at meaningful difference do not worry about hypotheses testing (unless you care about very very small differences)

06 Testing hypotheses 42 / 42 Agoston Reguly
